⑤ Improved antimicrobial coated implants.

⑦ Uniform adherent coatings of antimicrobial agents are applied to the surface of implants by applying a film of silicone oil to the surface of the implant and contacting the film-bearing surface with antimicrobial agents in a film-adherent form. A durable antimicrobial coating is formed. The coated implants can be packaged using mechanized implant handling equipment without significant loss of the antimicrobial coating.

EP 0 306 212 A2

IMPROVED ANTIMICROBIAL COATED IMPLANTS

This invention relates to improved implant devices. More particularly, this invention relates to an improvement in infection-resistant drug delivery implants. The coatings applied in accordance with this invention are better retained on the implant surface during mechanized implant packaging operations and are effective to prevent infection which may otherwise result after implantation of the device.

5 The use of controlled-release implants for administering estradiol to ruminant animals has been described in U.S. Patent No. 4,191,741. During implantation of such implants, conditions are typically unsanitary, causing infection which can result in loss of implants. Use of an antibiotic or germicide layer or coating on the surface of the implant to reduce infections and to improve implant retention has been described in U.K. Patent 2 136 688 A. The antibiotic coating facilitates parenteral administration of the
10 implants under non-sterile conditions; requirements for cleaning the implant needle, the site of implantation on the animal, and the implantation device are minimized or eliminated.

It is known that antimicrobial agents can be layered or coated onto the surface of an implant to inhibit infection at the site of implantation. However, some difficulties have been encountered in implementing that technology. Surface-applied antimicrobial agents have been found to be easily dislocated from the surface
15 of the implant by nominal mechanical manipulation of the implants, for example, during automated packaging operations. Loss of the antimicrobial coating dramatically reduces resistance to infection. Labor intensive recoating procedures and manual methods of packaging the antimicrobial coated implants have been employed to assure that implants have effective antimicrobial coatings at the time of administration. Even with added care during the implant manufacturing/packaging process, coating uniformity is difficult to
20 control.

Greater efficiencies in the manufacturing and packaging of implants as well as greater infection resistance at the implantation site would be realized with greater uniformity and implant-adherence of coatings of antimicrobial agents for implants. There is a need in the art for an improved method of coating implants to produce more uniform and more durable antimicrobial coatings on the implant surface, which
25 exhibit good stability during manufacture, handling, and storage, which allow immediate availability of the antimicrobial agents upon implantation and which do not interfere with the function of the implant.

In accordance with the present invention, a silicone fluid is employed to promote uniform adhesion of antimicrobial agents to the surface of an implant. The invention yields many advantages for the production and use of infection resistant implants. Greater efficiencies in implant manufacturing and processing
30 operations are possible. The adherent antimicrobial coating does not easily shake off the implant surface, allowing the implants to be subjected to the more rigorous conditions of automated packaging operations. Redusting or recoating procedures are eliminated. Because the use of present invention results in a more consistent and higher level application of antimicrobial agent, less quality control/analytical time is required during manufacturing operations. Further advantages include improved appearance of the implants and
35 coating consistency. Application of the coating of antimicrobial agent is not affected by normal variations in raw materials.

The present invention is based on the discovery that a silicone fluid can be applied to the exterior surface of an implant to improve the adherence of subsequently applied antimicrobial agents. The silicone fluid has a high affinity for the implant surface and spreads on the surface of the implant to form a thin film.
40 The film serves as a matrix-like carrier for subsequent applied antimicrobial agents, typically in a film-adherent powder or dust form. Antimicrobial agents contacting the silicone fluid layer are partially wetted by the fluid and retained on the surface of the implant.

In a preferred embodiment of the present invention an adherent antimicrobial coating is applied to an implant comprising an anabolic agent in a silicone polymer matrix adapted for sustained-release of the
45 anabolic agent. The silicone fluid does not affect adversely either the safety or efficacy of the implant. The rate of diffusion of the anabolic agent from the implant remains essentially unchanged after coating in accordance with this invention.

The improved implant coatings of this invention comprise a silicone fluid in contact with the surface of the implant and an antimicrobial agent in contact with the silicone fluid. The nature of the implant is not
50 critical to the present invention, however the improved coatings are particularly suited for implants having surfaces formed from biocompatible silicone based polymers. The implants can assume any one of a variety of alternate constructions and can be used for prosthetic purposes or as reservoirs or matrices for the sustained release of biologically active compounds. They can be formed entirely of a silicone polymer, for example by extrusion, molding and/or machining, or they can be fabricated by coating an implant core, constructed of an art-recognized biocompatible implant material or material composite, with a silicone

polymer material.

Representative silicone polymers suitable for implant construction are diphenylpolysiloxane, dimethylpolysiloxane (dimethicone), phenylmethylpolysiloxane, trifluoropropylmethylsiloxane, polydimethylsiloxane copolymerized with polyethylene oxide, copolymers of dimethylpolysiloxane and polymethylmethacrylate and mixtures thereof.

Preferred implants which can be coated in accordance with this invention are those constructed in accordance with the disclosure of U.S. Patent No. 4,191,741 issued March 4, 1980, the disclosure of which is expressly incorporated herein by reference. The implants described in that patent are designed for the controlled release administration of anabolic agents to ruminant animals. Exemplary of anabolic agents which can be released from such implants are estradiol, anabolic estradiol derivatives, including estradiol dipropanate, estradiol benzoate, estradiol valerate and the like, trenbolone acetate and certain resorcinol lactones including zeranol and zearalenone.

The improved antimicrobial coatings of this invention are applied to implant surfaces by first applying a silicone fluid to form a film in contact with the surface of the implant and subsequently contacting the film-bearing implant surfaces with an antimicrobial agent. Preferably the antimicrobial agent is in a film-adherent powder or dust form. The silicone film has a high affinity for the implant surface and for the antimicrobial agent and serves as a fluid matrix which wets and effectively binds the antimicrobial agent to the implant surface. The effectiveness of the silicone fluids for providing a base for the uniform adherent antimicrobial coatings of this invention derives from its high affinity both for the implant surface and for the antimicrobial agent itself.

Polydimethylsiloxane fluids and vulcanizing polydimethylsiloxane systems have been found to be especially suitable for use in forming the coatings in accordance with this invention. Such fluids are chemically equivalent to the silicone polymers from which the implants are preferably constructed. The silicone fluid therefore does not interfere with or affect implant safety or efficacy. Nor does it affect the availability of the antimicrobial agent at the implantation site.

Generally, the dimethylpolysiloxanes are low volatility liquids having a viscosity such that it will form thin silicone oil coating on the implant surfaces at ambient temperature. Preferred among the several commercially available silicone fluids is a high consistency medical grade fluid sold by Dow Corning Corporation under the designation 360 Medical Fluid. Dow Corning® 360 Medical Fluid is available in viscosities ranging from 20 centistokes to 12,500 centistokes (measured at 77°F.). Preferably the silicone fluid should have a viscosity range between about 200 and about 500 centistokes. A silicone fluid having a viscosity of about 350 centistokes has produced excellent results. Silicone oils with such viscosities exhibit a low volatility at room temperature and readily spread across the implant surface to form a thin fluid film in contact with the implant surface.

Implants can be coated with the polydimethylsiloxane liquid using art-recognized coating techniques such as by dipping or spraying. A coating pan can be used and offers advantages where a multiplicity of uniform implants are to be coated in a single batch. The silicone fluid is applied to the implant surface at a rate of about 0.1 to about 0.6 mg per cm² of implant surface. The optimum rate of application will depend on the viscosity of the applied fluid and the nature and condition of the implant surface. Where the silicone fluid has a viscosity of about 350 centistokes it is applied to the implant surface at a rate of about 0.2 to about 0.5 mg per cm² of implant surface. In a coating pan environment, the silicone fluid can be added to a batch of implants, for example cylindrical implants of uniform size, and will rapidly spread to cover the surfaces of the implants with a thin film of silicone fluid.

The silicone film bearing implants are then contacting with an antimicrobial agent having affinity for the silicone film. Preferably the antimicrobial agent is in the form of a dust or powder which when brought into contact with the film bearing implant surface is partially wetted by the fluid film and thereby effectively bound to the implant surface.

For the purpose of defining this invention, the term antimicrobial agent shall include antibiotic, antimicrobial, antibacterial, germicidal agents and the like. The antimicrobial coating may comprise a combination of antimicrobial agents. Typical antibiotics which may be used in the invention include: aminoglycosides, such as gentamicin, kanamycin, neomycin, paromomycin, streptomycin, or tobramycin; ansamycins, such as rifamycin, or rifampin; cephalosporins, such as cephalexin, cephaloridine, cephalothin, defazolin, cephapirin, cephradine, or cephaloglycin; chloramphenicols; macrolides, such as erythromycin, tylosin, oleandomycin, or spiramycin; penicillins, such as penicillin G & V, phenethicillin, methicillin, oxacillin, cloxacillin, dicloxacillin, floxacillin, nafcillin, ampicillin, amoxicillin, or carbenicillin; sulfonamides; tetracyclines, such as tetracycline, oxytetracycline, chlortetracycline, methacycline, demeclocycline, rolitetracycline, doxycycline, or minocycline; trimethoprim-sulfamethoxazole; polypeptides, such as bacitracin, polymyxins, tyrothricin, or vancomycin; and miscellaneous antibiotics, such as lincomycin,

clindamycin, or spectinomycin. A preferred antibiotic is oxytetracycline hydrochloride (OTC).

Typical germicides which may be used in this invention include phenols; cresols; resorcinols; substituted phenols; aldehydes; benzoic acid; salicylic acid; iodine; iodophors, such as betadine; chlorophors, such as hypochlorites; peroxides; such as hydrogen peroxide and zinc peroxide; heavy metals and their salts, such as merbromin, silver nitrate, zinc sulfate; surface-active agents, such as benzalkonium chloride; furan derivatives, such as nitrofurazone; sulfur and thiosulfates; salicylanilides; and carbanilides. Preferred germicides include betadine, iodine, silver nitrate and furan derivatives, such as nitrofurazone.

The amount of the antibiotic or germicide to be used to form the present coating varies with the nature of antibiotics or germicides employed and to some extent the method of coating application. For example, the amount of antibiotic can range from about 0.1 mg per cm² to about 2.1 mg per cm², with the preferred range being from about 0.2 mg to about 0.8 mg per cm². The typical range of the amount of germicide used is exemplified by betadine, which has a range of about 0.5 mg to about 5.2 mg per cm², and by nitrofurazone, which has a range of about 2.0 µg to about 8.3 µg per cm². The preferred ranges of betadine and nitrofurazone are: about 0.5 mg. to about 1.0 mg per cm²; and about 2.1 µg to about 4.1 µg per cm², respectively. Effective amounts of oxytetracycline hydrochloride range from about 0.1 mg to 2.1 mg per cm², preferably from about 0.1 to about 1.0 mg per cm² and, more preferably, from about 0.14 to about 0.5 mg per cm².

Preferably, the antibiotic or germicide is in a particulate or powdered form ranging in particle size from about 325 mesh (45 µm) to about 60 mesh (250 µm) and more preferably from about 325 mesh (45 µm) to about 200 mesh (75 µm). Commercially available antibiotic powders can be milled to produce the desired particle size distribution.

EXAMPLE 1

Implants sold under the trademark COMPUDOSE® 200 were used to evaluate applications of polydimethylsiloxane liquid based coatings of oxytetracycline hydrochloride (OTC). COMPUDOSE® 200 designates an implant which is 3 cm in length and 4.76 mm in diameter. This diameter includes an inert core and a 250 micron coating containing about 24 mg of estradiol, the active ingredient. The surface area is 4.84 cm² and the device delivers estradiol continuously for about 200 days. The implant is sold by Elanco Products Company, a Division of Eli Lilly and Company.

Evaluation results are summarized in Table 1. All implants were dusted in a coating pan with OTC at a rate of 2.5 mg OTC/implant. Predusting treatment was varied as follows: no pretreatment in Trials 1 and 2; pretreatment with 1% fumed silica (Aerosil®) in Trial 3; and pretreatment with Dow Corning® 360 Medical Fluid (viscosity = 350 cs at 77° F.) for Trials 4-6.

TABLE 1

Oxytetracycline Hydrochloride Retention Results				
Trial	Pre-Dusting Treatment	Visual Observation of OTC Coating	Mean Value mg OTC/Implant	SD ¹
1	None	Uneven OTC Coating	--	--
2	None	Uneven OTC Coating	0.8	0.19
3	1% Fumed Silica	Uneven OTC Coating	0.8	0.41
4	2 mg/Implant Silicone Spray	Very Even OTC Coating	1.6	0.15

6	2 mg/Implant Silicone Spray (added to empty coating pan) followed by implants	Very Even OTC Coating	1.8	0.31

1 -- indicates no values reported.

2 Standard deviation from mean value

The results demonstrate unequivocally the advantage offered by pretreatment of implants with a film-forming silicone fluid prior to dusting with antibiotic. It not only enhances the overall rate of retention of antibiotic on the implant surface, but it also enhances coating uniformity within the lots of coated implants. Moreover, visual inspection reveals an even coating and one that is retained during manipulation of the implants in automated packaging equipment utilizing vibratory bowls to align and distribute the implants into the individual package cavities.

EXAMPLE 2

Three successive lots of COMPUDOSE® 200 implants (approximately 26,000 implants, each) were coated in accordance with this invention. Treatment consisted of placing the implants in a coating or dusting pan and adding approximately 50 g of dimethicone (2 mg dimethicone/implant) followed by 65 g of oxytetracycline hydrochloride and tumbling until the implants appeared to be uniformly coated. For each of the three lots, implants were randomly selected, packaged, and submitted for evaluation. The results are summarized in Table 2.

Claims

1. An implant adapted for the controlled release of an anabolic agent, said implant comprising a silicone polymer matrix, an anabolic agent in said polymer matrix, and an antimicrobial coating, wherein the coating
5 comprises a silicone fluid and an antimicrobial agent in contact with said fluid.
2. An implant as claimed in Claim 1, wherein the anabolic agent is estradiol.
3. An implant as claimed in Claim 1, wherein the antimicrobial agent agent is oxytetracycline hydrochloride.
4. An implant as claimed in any one of Claims 1 to 3, wherein the silicone polymer matrix and anabolic
10 agent form a coating surrounding a biocompatible inert core.
5. An implant as claimed in Claim 4, wherein the anabolic agent is estradiol.
6. An implant as claimed in any one of Claims 1 to 5, wherein the silicone fluid has a viscosity of about 200 to about 500 centistokes.
7. An implant as claimed in any one of Claims 1 to 6, wherein the silicone fluid is in contact with the
15 surface of said silicone polymer matrix implant and the antimicrobial agent is in contact with said silicone fluid.
8. A method of preparing an implant adapted for the controlled release of an anabolic agent, comprising coating a silicone polymer matrix, containing an anabolic agent, with an antimicrobial coating, wherein the coating comprises a silicone fluid and an antimicrobial agent in contact with said fluid.
9. A method according to Claim 8 comprising applying a silicone fluid to form a silicone film in contact
20 with the surface of the silicone polymer matrix and then contacting the film-bearing surface with an antimicrobial agent in a film-adherent powder form.
